# VARMA(1,1) models

### VARMA(1,1)

$$x_t - \Phi x_{t-1} = u_t - \Theta u_{t-1}$$

 $egin{aligned} & x_t = ext{observed variable} \in \mathbb{R}^d \ & u_t = ext{white noise (enough to assume uncorrelated)} \in \mathbb{R}^d \ & \Phi, \Theta \in \mathbb{R}^{d imes d}, \ & 
ho(\Phi) < 1, \ & 
ho(\Theta) < 1 \end{aligned}$ 

Many known models to simulate volatility reduce to VARMA(1,1):

- GARCH(1,1)
- Multivariate stochastic volatility models

# Estimating VARMAs

#### Problem

Given enough observations ( $x_t$ ) generated by a VARMA, determine parameters  $\Phi$ ,  $\Theta$ 

A common choice is **QML** (quasi-maximum-likelihood):

- Assume ut Gaussian independent
- Siven guesses  $\hat{\Phi}, \hat{\Theta}$ , compute likelihood  $\ell(\hat{\Phi}, \hat{\Theta})$  of generating the given time series
- Seed ℓ(·, ·) into a black-box minimization procedure (e.g., Matlab's fminunc)

## Problems with QML

- Costly: each function evaluation costs O(nd<sup>3</sup>), with n = length of time series. Hundreds or thousands required
- Black-box: difficult to implement and tweak, and understand what's going on.
- No convergence guarantees, non-convex optimization problem in many variables
- Hey doc, what if our ut isn't Gaussian independent?

### Our attempt

Moments estimator: determine  $\Phi, \Theta$  as a function of the autocovariances

$$M_k = \mathbb{E}_{\mathsf{t}}\left[x_t x_{t+k}^{\mathsf{T}}\right]$$

 $(\mathbb{E}_{t} [\cdot] := stationary limit mean)$ 

The  $M_k$  contain cov's among all variables of the time series, e.g., (d = 3)

$$x_{t} = \begin{bmatrix} a_{t} \\ b_{t} \\ c_{t} \end{bmatrix} \Rightarrow M_{k} = \begin{bmatrix} \mathbb{E}_{t} [a_{t}a_{t+k}] & \mathbb{E}_{t} [a_{t}b_{t+k}] & \mathbb{E}_{t} [a_{t}c_{t+k}] \\ \mathbb{E}_{t} [b_{t}a_{t+k}] & \mathbb{E}_{t} [b_{t}b_{t+k}] & \mathbb{E}_{t} [b_{t}c_{t+k}] \\ \mathbb{E}_{t} [c_{t}a_{t+k}] & \mathbb{E}_{t} [c_{t}b_{t+k}] & \mathbb{E}_{t} [c_{t}c_{t+k}] \end{bmatrix}$$

### Moment estimator

We will show  $(\Phi, \Theta) = f(M_0, M_1, M_2)$ 

### GMM estimator

• Compute sample 
$$\hat{M}_k = \frac{1}{n} \sum x_t x_{t+k}^T$$
  
• Get  $(\hat{\Phi}, \hat{\Theta}) = f(\hat{M}_0, \hat{M}_1, \hat{M}_2)$ 

- Very fast: working only with  $d \times d$  matrices, no dependence on n (after computing moments)
- Asymptotically consistent and normal, under suitable conditions
- In simulated experiments, not as accurate as QML, but good as initial value

Already known for univariate GARCH; generalization requires some linear algebra machinery

## Yule-Walker results

The parameter  $\Phi$  is easy to obtain:

Theorem

 $\Phi = M_{k+1}M_k^{-1}$  for each  $k \ge 1$ 

In particular  $\Phi = M_2 M_1^{-1}$ 

Proof:

$$\underbrace{\mathbf{x}_{t-k-1}(\mathbf{x}_t - \mathbf{\Phi}\mathbf{x}_{t-1})^T}_{=M_{k+1} - \mathbf{\Phi}M_k} = \underbrace{\mathbf{x}_{t-k-1}(u_t - \mathbf{\Theta}u_{t-1})^T}_{=0 \text{ if } k \ge 1}$$

### Estimating $\Theta$

Let 
$$r_t = x_t - \Phi x_{t-1} = u_t - \Theta u_{t-1}$$
,  $Y := \mathbb{E}\left[u_t u_t^T\right]$ 

$$\Gamma_{0} := \mathbb{E}_{t} \left[ r_{t} r_{t}^{T} \right] = M_{0} - \Phi M_{1}^{T} - M_{1} \Phi^{T} + \Phi M_{0} \Phi^{T} = \mathbf{Y} + \Theta \mathbf{Y} \Theta^{T}$$
$$\Gamma_{1} := \mathbb{E}_{t} \left[ r_{t} r_{t+1}^{T} \right] = M_{1} - \Phi M_{0} = -\Theta \mathbf{Y}$$

Blue expressions allow us to compute  $\Gamma_0$ ,  $\Gamma_1$ . Use them + red expressions to decouple equations for Y,  $X = \Theta^T$ 

$$\Gamma_0 = Y + \Gamma_1 Y^{-1} \Gamma_1^T$$
  
$$\Gamma_1^T + \Gamma_0 X + \Gamma_1 X^2 = 0$$

### Existence and unicity

$$\Gamma_0 = Y + \Gamma_1 Y^{-1} \Gamma_1^T$$
  
$$\Gamma_1^T + \Gamma_0 X + \Gamma_1 X^2 = 0$$

Studied by matrix equation people (like me)

#### Existence and unicity

- Solution exists if Q(λ) := Γ<sub>1</sub><sup>T</sup>λ<sup>-1</sup> + Γ<sub>0</sub> + Γ<sub>1</sub>λ is such that Q(λ) > 0 for each λ on unit circle
- Solution unique if we ask Y > 0,  $\rho(X) < 1$  (as was assumed)

Of course, if the model is well-posed, there must be a solution...

### How to solve matrix equations

Let us focus on  $\Gamma_1^T + \Gamma_0 X + \Gamma_1 X^2 = 0$ Solution resembles a lot linear recurrence theory

Generalized eigenvalues/Vectors of the problem:

$$(\lambda, \mathbf{v})$$
 s.t.  $(\Gamma_1^T + \Gamma_0 \lambda + \Gamma_1 \lambda^2)\mathbf{v} = 0$ 

(there are 2*d* of them!)

#### Theorem

Solutions can be eigendecomposed as  $X = VDV^{-1}$ V contains d of the 2d eigenvectors of the problem, D diagonal with eigenvalues

## Generalized eigenvalues

#### Companion matrix

Eigenvalues/eigenvectors are in 1:1 correspondence with those of the linearization matrix

$$\begin{bmatrix} 0 & I_d \\ -\Gamma_1^{-1}\Gamma_1^T & -\Gamma_1^{-1}\Gamma_0 \end{bmatrix}$$

Matrix version of the "companion matrix" for polynomials

#### Palindromic matrix polynomials

Due to the structure in 
$$\Gamma_1^T + \Gamma_0 \lambda + \Gamma_1 \lambda^2$$
,  $\Gamma_0 = \Gamma_0^T$ , eigenvalues come in pairs  $(\lambda, \lambda^{-1})$ 

Good for us — we needed d of them with |d| < 1!

## To sum up

- **①** Get sample moments  $M_0, M_1, M_2$
- 2 Get  $\Phi = M_2 M_1^{-1}$
- **3** Compute  $\Gamma_0$ ,  $\Gamma_1$

• Get eigenvalues/vectors of 
$$\begin{bmatrix} 0 & I_d \\ -\Gamma_1^{-1}\Gamma_1^T & -\Gamma_1^{-1}\Gamma_0 \end{bmatrix}$$

- **(**) Take those with  $\lambda$  inside the unit circle
- Assemble  $\Theta^T = X = VDV^{-1}$

### What can go wrong

Sometimes, no stationary/invertible model with autocovariances  $\hat{M}_i$ 

#### Existence and unicity

• Solution X, Y exists if  $Q(\lambda) := \Gamma_1^T \lambda^{-1} + \Gamma_0 + \Gamma_1 \lambda$  is such that  $Q(\lambda) > 0$  for each  $\lambda$  on unit circle

Must hold with exact  $\Gamma_i$ , but sample  $\hat{\Gamma}_i$  might give inconsistent data  $\Rightarrow$  Perturb  $M_0$ ,  $M_1$ ,  $M_2$  to ensure solvability!

Figure: Diagonal GARCH, d = 2,  $\rho(\Theta) = 0.6$ , n = 1000

Figure: Diagonal GARCH, d = 2,  $\rho(\Theta) = 0.6$ , n = 1000

Figure: Diagonal GARCH, d = 2,  $\rho(\Theta) = 0.7$ , n = 1000

Figure: Diagonal GARCH, d = 3,  $\rho(\Theta) = 0.6$ , n = 1000

Figure: Diagonal GARCH, d = 3,  $\rho(\Theta) = 0.6$ , n = 1000, larger off-diagonal elements

Poloni, Sbrana (Pisa, Rouen)

Figure: Diagonal GARCH, d = 3,  $\rho(\Theta) = 0.6$ , n = 500

Figure: Diagonal GARCH, d = 2,  $\rho(\Theta) = 0.7$ , n = 500

Figure: Diagonal GARCH, d = 2,  $\rho(\Theta) = 0.7$ , n = 5000

### Possible improvements

- Improve solvability enforcement (work on  $\Theta$  and  $\Phi$  at the same time)
- Combine with an iterative ML-like optimization e.g., GLS (generalized least squares) for GARCH?
- More intensive testing & applications

### Possible improvements
